

Operator Console

Guide 6 of 6

TL;DR

The Operator Console is the founder-only surface of last resort: the kill switches, the live-authorization toggles, deletion requests, replication outreach drafts, and the diagnostic loops. None of it is needed in a normal day. All of it should be reachable in under thirty seconds when something is wrong. This guide is the map.

You will need

- A signed-in Codex session with operator privileges.
- Shell access to the host that runs the `launched currents-api` and `currents-scheduler` services (for the `env-var` kill switches).
- The runbooks under `docs/operations/` open in a separate tab.

This guide does NOT cover

- How Currents, the Oracle, and Forecasts produce their normal output — Guides 3–5.
- Routine triage of principles — Guide 2.
- Security architecture in the abstract; see `docs/security/Threat_Model.md`.

1 Map of the console

The console is not one page. It is a small set of operator-only routes inside the Codex plus a small set of environment variables on the host. The routes:

- `/(authenticated)/ops` — top-level operator surface. Scheduler health, ingestion toggles, recent error counts.
- `/(authenticated)/admin` — administrative actions: user / org management, deletion requests, retraction workflow.
- `/(authenticated)/founder-currents` — per-opinion controls for Currents (revoke, hold, edit event metadata).
- `/(authenticated)/forecasts` (with operator role) — per-row `liveAuthorizedAt` toggles and perbet confirmation modals.
- `/(authenticated)/publication` — the publication review queue; `PublicationReview` actions including unpublish.
- `/(authenticated)/social` — replication outreach drafts and manual external posting controls.

[screenshot `screenshots/06_operator_dashboard.png` not yet captured — The `/ops` dashboard, showing scheduler health and the kill-switch state for each ingestion path.]

2 Kill switches

There is no global kill switch. There are several precise ones, and that is deliberate. Each disables one specific risky surface.

- `CURRENTS_X_INGESTION_DISABLED=true` — Currents X ingestion. Causes the next scheduler cycle to log `currents.x_ingestion.disabled reason=manual_kill_switch` and write no new events. Clearing `X_BEARER_TOKEN` has the same effect.
- `ARTICLES_ENABLED=false` — the long-form article dispatcher. Existing articles stay up; no new ones are clustered or written.
- `FORECASTS_LIVE_TRADING_ENABLED=false` — the master live-trading flag from Guide 5. Setting this to false disables gate 5 of the eight-gate contract and refuses every downstream submit.
- `FORECASTS_KILL_SWITCH=true` — the per-submit kill switch (gate 8). Re-checked immediately before each order placement; trips even bets that already passed operator confirmation.

After flipping any of these, restart the affected service. For the local `launchd` Currents runtime, the procedure is documented in `docs/operator/CURRENTS.md` §“Bringing Currents to life” and the helper script `./scripts/refresh-local-currents-runtime.sh -restart -health-check`.

3 Live authorization, revoked

The inverse of gates 6–7 in Guide 5. Operator routes:

- **Revoke per-prediction authorization.** On the forecast card, click **Revoke live authorization**. `liveAuthorizedAt` is cleared. The row drops out of the public grid (the row is publicly visible iff `liveAuthorizedAt IS NOT NULL`).
- **Cancel an open order before fill.** For exchanges that permit cancel, the operator UI exposes a cancel button on the position row. The submitter logs the cancel; the position rolls back.
- **Close an existing position.** The portfolio view has a manual close action. This is a real-funds action; it is gated behind the same confirmation modal as opening a bet.

4 Deletion requests and retractions

Two adjacent flows; understand the difference before using them.

- **Deletion** (`/admin`) — removal of source material. Soft-deletes the upload (`deletedAt` set); all derived claims, conclusions, and citations are cascade-marked. The public surface stops resolving the affected rows. Use for: user / subject deletion requests; legal or compliance reasons.
- **Retraction** (`/publication`) — removal of a published output. The retraction is itself a published artifact: it creates a new `PublishedConclusion` row that retracts the previous version, leaving an audit trail. Use for: an article or conclusion the firm no longer endorses.

A retraction is a stance. A deletion is a removal of evidence. Do not confuse them.

5 Replication outreach drafts

`/ (authed) /social` contains the operator-drafted outreach threads that go out to external replicators, journalists, and collaborators. The page generates a draft from the firm’s recent public material;

the operator edits and either posts manually or exports for sending through a separate channel.

Preview — partially shipped

Automated sending is not enabled. Today, the outreach surface is a draft generator plus a send-when-I-say-so review queue. Operator authorization for automated outreach posting is intentionally not shipped; see the social outbound roadmap.

6 Diagnostic loops

The fastest way to localize a problem before flipping a switch:

- `python noosphere/scripts/diagnose_currents_pipeline.py` — the Currents non-writing diagnostic. Booleans and counts only; never prints secrets.
- **OperatorPulse** card on the founder dashboard — Currents ingestion health, color-coded.
- `/ops` — recent error counts per scheduler loop.
- `docs/operator/SCHEDULER_OPS.md` — the scheduler operator reference.
- `docs/security/Threat_Model.md` — the explicit list of which surfaces are allowed to do what.

7 The one-page checklist when something is wrong

1. Look at the dashboard. Is **OperatorPulse** red? What does the red text say?
2. Run the relevant non-writing diagnostic (`diagnose_currents_pipeline.py` for Currents; the equivalent forecasts diagnostic for the trading surface).
3. If a kill switch is the right answer, flip the most specific one. Do not disable broader surfaces than you need to.
4. Restart the affected service with the documented helper script; do not stop the entire stack.
5. Once stable, file a critique through `/critiques` so the failure has a written record.

8 Where the docs are

- `docs/operator/CURRENTS.md` — Currents operator notes.
- `docs/operator/SCHEDULER_OPS.md` — scheduler ops.
- `docs/operator/public_surfacing.md` — public-surface predicates.
- `docs/operations/Forecasts_Founder_Alpha_Runbook.md` — the live-trading runbook.
- `docs/security/Threat_Model.md` — threat model.

Where to read next

This is the last of the six guides. After this, the right reading is the runbooks under `docs/operations/`: the scheduler, the forecasts portfolio setup, and the founder-alpha runbook. The next scheduled task you should set up is a weekly fifteen-minute slot for principle triage (Guide 2) and a daily one-minute glance at **OperatorPulse**.
