

Calibrated narrowing under uncertainty: a firm cluster

Cluster bayesian-update-12a26716

Theseus Auto-Paper Generator

May 2026

Disclosure: machine-drafted, founder-reviewed.

Lead conclusion: `conclusion-calibration-over-coverage-1`.

Methodology root: `profile-calibration-over-coverage-1` (bayesian-update).

Abstract

This paper distills 3 firm conclusion(s) anchored on `conclusion-calibration-over-coverage-1`, all sharing the methodology root "Calibrated narrowing under uncertainty". The cluster's claims are stress-tested against 2 resolved forecast(s) drawn from the firm's calibration ledger. Lead claim: A calibrated narrow claim beats a confident broad claim when the firm must commit; we will revisit if a resolved forecast contradicts the narrowing.

1 Introduction

The Theseus engine routinely produces firm conclusions, attaches them to a methodology profile, and tracks how those conclusions perform when their predictive consequences are settled in public forecast markets. This paper presents one such cluster of 3 conclusion(s), drawn together by their shared methodology root and by at least one resolved forecast that touches the cluster. The cluster's lead claim states: "A calibrated narrow claim beats a confident broad claim when the firm must commit; we will revisit if a resolved forecast contradicts the narrowing."

Conclusions in this cluster

- **conclusion-calibration-over-coverage-1** [row:conclusion:conclusion-calibration-over-coverage-1]
— A calibrated narrow claim beats a confident broad claim when the firm must commit; we will revisit if a resolved forecast contradicts the narrowing.
- **conclusion-calibration-over-coverage-2** [row:conclusion:conclusion-calibration-over-coverage-2]
— Reliability priors should decay toward the base rate when the regime shifts, by 2026 Q4 at the latest.
- **conclusion-calibration-over-coverage-3** [row:conclusion:conclusion-calibration-over-coverage-3]
— When forced to choose, the firm publishes the calibrated claim and files the broad one as an open question.

2 Methods

The cluster shares a single methodology root, *Calibrated narrowing under uncertainty* (profile-calibration-over-pattern bayesian-update).

Summary. Resolve a broad question into the narrowest claim the evidence actually licenses, then widen only as resolved forecasts justify it.

Reasoning moves

- anchor on the base rate before reading the signal
- prefer the narrow calibrated claim to the broad confident one
- widen the claim only when a resolved forecast licenses it

Assumptions

- signals are conditionally independent given the regime
- the base rate is stationary over the forecast horizon

3 Results

The cluster’s conclusions were stress-tested against 2 resolved forecast(s) from the firm’s calibration ledger. Each row below resolves to a database record.

Headline	Outcome	Stated	Brier	Row
Calibrated narrowing under uncertainty: claim 1 holds	YES	0.70	0.090	[row:forecast_resolution:prediction]
Calibrated narrowing under uncertainty: claim 2 holds	YES	0.70	0.090	[row:forecast_resolution:prediction]

Across the 2 fully-scored forecast(s) above, the firm achieved a mean Brier score of 0.090. Each contributing row is auditable via its \rowref{...} marker.

4 Discussion

Reviewer firm-peer-review on conclusion-calibration-over-coverage-1: verdict revise (confidence 0.78).

Peer-review findings

- **minor** — One supporting signal rests on a single source; triangulate before widening the claim.
[row:review_report:review-calibration-over-coverage-seed]

5 Limits and failure modes

The methodology root carries a registered failure-mode catalog. Every limit below is an entry from the firm’s catalog, not a synthesized observation.

- regime change invalidates the stationarity assumption
- common-mode bias across correlated signals
- narrowing past the point the evidence supports
